

# Novel approaches for nonlinear evolution equations based on operator splitting

Mechthild Thalhammer  
Leopold-Franzens-Universität Innsbruck, Austria

Heidelberg, Germany, September 2025

# Acknowledgements

**Acknowledgements.** The contents of this talk are based on recent and current investigations in collaboration with

- Sergio Blanes (Valencia, Spain),
- Fernando Casas (Castellón, Spain),
- Cesáreo González (Valladolid, Spain).

Additional inspiration comes from joint research activities with

- Barbara Kaltenbacher (Klagenfurt, Austria),
- José Antonio Carrillo (Oxford, United Kingdom),
- Hanns-Christoph Nägerl, Manuele Landini (Innsbruck, Austria).

# Opening statements

## Time integration methods.

- Exponential operator splitting methods constitute a favourable class of time integration methods for differential equations.
- Numerous contributions demonstrate their substantial advantages over standard approaches regarding reliability and efficiency.
- The preservation of conserved quantities over amplified timeframes justifies the perception as geometric numerical integrators.
- The design, theoretical analysis, and practical implementation for specific applications continues to be an active area of research.

# Opening statements

## Scope of applications.

- Exponential operator splitting methods are appropriate for a broad variety of **relevant applications**.
- This includes **Hamiltonian systems** (classical mechanics) as well as **Schrödinger equations** (quantum mechanics), where the advantages of geometric numerical integrators become apparent.
- The scope naturally extends to high-order **reaction-diffusion systems** and **complex Ginzburg–Landau-type equations** forming beautiful **spatio-temporal patterns** (biology, chemistry, geology, physics), higher-order **damped wave equations** (nonlinear acoustics), and **kinetic equations** (plasma physics).

# Class of problems

**Class of problems.** We focus on **partial differential equations** that comprise linear combinations of powers of the **Laplace operator**, **space-dependent functions**, and **nonlinear multiplication operators**

$$\begin{cases} \partial_t U(x, t) = \sum_{k=0}^K \alpha_k \Delta^k U(x, t) + W(x) U(x, t) + f(U(x, t)), \\ U(x, t_0) = U_0(x), \quad (x, t) \in \Omega \times [t_0, T] \subset \mathbb{R}^d \times \mathbb{R}. \end{cases}$$

We perform **short-term** as well as **long-term** simulations for relevant **model problems** in  $d \in \{1, 2, 3\}$  space dimensions.

- High-order **reaction-diffusion** equations (quasicrystals)
- Complex **Ginzburg–Landau** equations (superconductivity)
- **Gross–Pitaevskii** equations (Bose–Einstein condensates)

# General formulation

**General formulation.** Setting  $u(t) = U(\cdot, t)$  for  $t \in [t_0, T]$  and assigning linear differential operators as well as nonlinear multiplication operators

$$(A v)(x) = \sum_{k=0}^K \alpha_k \Delta^k v(x), \quad (B(v))(x) = W(x) v(x) + f(v(x)), \quad x \in \Omega,$$

we obtain compact reformulations as nonlinear evolution equations

$$\begin{cases} \frac{d}{dt} u(t) = F(u(t)) = A u(t) + B(u(t)), \\ u(t_0) = u_0, \quad t \in [t_0, T], \end{cases}$$

which indicate natural decompositions into two subproblems.

# Splitting approach

**Splitting approach.** Exponential operator splitting methods for nonlinear evolution equations of the form

$$\begin{cases} \frac{d}{dt} u(t) = F(u(t)) = F_1(u(t)) + F_2(u(t)), \\ u(t_0) = u_0, \quad t \in [t_0, T], \end{cases}$$

rely on the presumption that the numerical approximation of the associated subproblems

$$\frac{d}{dt} u_1(t) = F_1(u_1(t)), \quad \frac{d}{dt} u_2(t) = F_2(u_2(t)),$$

is significantly simpler compared to the numerical approximation of the original problem.

# Splitting approach

**Classical notation.** The **exact evolution operator** associated with the original problem is denoted by

$$\mathcal{E}_{t,F}(u_0) = u(t), \quad t \in [t_0, T],$$

that is, we indicate the dependence on the current time, the defining operator, and the initial state.

**Alternative notation.** The alternative **formal notation**

$$e^{tD_F} u_0 = u(t), \quad t \in [t_0, T],$$

is justified by the **calculus of Lie-derivatives**. This calculus is most useful with regard to the **convergence analysis** of **complex** exponential operator splitting methods and the **design** of **(processed) modified** operator splitting methods, since it **reveals analogies** between linear and nonlinear cases.

# Splitting approach

**Time-stepping approach.** We aim at the computation of numerical approximations at certain time grid points based on a standard time-stepping approach (recurrences for **exact** and **numerical** solution values)

$$\begin{aligned} t_0 < t_1 < \dots < t_N = T, \quad \tau_n = t_{n+1} - t_n, \\ u_{n+1} = \mathcal{S}_{\tau_n, F}(u_n) \approx u(t_{n+1}) = \mathcal{E}_{\tau_n, F}(u(t_n)), \\ n \in \{0, 1, \dots, N-1\}. \end{aligned}$$

**Standard splitting methods.** Any **standard** exponential operator splitting method can be cast into the following form with **real coefficients**

$$\mathcal{S}_{\tau, F} = \mathcal{E}_{\tau, b_s F_2} \circ \mathcal{E}_{\tau, a_s F_1} \circ \dots \circ \mathcal{E}_{\tau, b_1 F_2} \circ \mathcal{E}_{\tau, a_1 F_1}, \quad (a_j, b_j)_{j=1}^s \in \mathbb{R}^{2s}.$$

# On firm ground

**On firm ground.** The **excellent behaviour** of (optimised) exponential operator splitting methods with respect to stability, accuracy, efficiency, and the preservation of conserved quantities over long timeframes has been confirmed by a variety of contributions.

## **Selection of comprehensive descriptions and specific studies.**

- Open access review of S. Blanes, F. Casas, A. Murua on **splitting methods for differential equations** (Acta Numerica 33, 2024).
- Hairer, Lubich, Wanner (2006), McLachlan, Quispel (2002), Sanz-Serna, Calvo (2018).
- Auzinger, Hofstätter, Koch (2019), Bao, Jin, Markowich (2002), Bertoli, Besse, Vilmart (2021), Caliari, Zuccher (2021), Castella, Chartier, Decombes, Vilmart (2009), Chin (1997), Danaila, Protas (2017), Goth (2022), Hansen, Ostermann (2009), Jahnke, Lubich (2000), Kieri (2015), Kozlov, Kvaerno, Owren (2004), Omelyan, Mryglod, Folk (2003), Strang (1968), Trotter (1959), Yoshida (1990).

# Alternative approaches

**Alternative approaches.** Despite the benefits of standard exponential operator splitting methods, it remains an issue of substantial interest to exploit **alternative approaches**, amongst others,

- to **overcome** a **second-order barrier** valid for **stable** exponential operator splitting methods applied to **non-reversible systems**,
- to **gain** additional **freedom** in the adjustment of the method coefficients for the **design** of **optimised** schemes.

**The investigation of these fundamental questions  
reveals surprising findings ...**

# Alternative approaches

- **Complex operator splitting methods.** The inclusion of **complex coefficients** permits the design of **stable high-order** exponential operator splitting methods with specific **structural features**.
- **Modified operator splitting methods.** Modifications of standard exponential operator splitting methods are expedient for our model problems of complex Ginzburg-Landau type, since the **nonlinear multiplication operators**  $F_2$  and the **iterated commutators**

$$[D_{F_2}, [D_{F_2}, D_{F_1}]] = F_1'' F_2 F_2 + F_1' F_2' F_2 + F_2' F_2' F_1 - F_2'' F_1 F_2 - 2 F_2' F_1' F_2$$

have **similar structures**.

# Adaptive modified operator splitting methods

Gross–Pitaevskii equations

Groundstate computation, Time evolution

Bose–Einstein condensation

# Numerical experiments

**Summary.** Design of a **stable** and **efficient** fourth-order exponential operator splitting method based on the incorporation of an **iterated commutator**.

Severe stability issues for a standard fourth-order splitting method applied to linear (up) and nonlinear (down) problems of parabolic type (left).

# Numerical experiments

**Questions.** Favourable behaviour of a fourth-order modified operator splitting method for linear and nonlinear Schrödinger-type equations over longer times? Benefits of a simple local error control based on the second-order Strang splitting method?

Linear (up) versus nonlinear (down) cases.  
Solution profiles  $\Re(\psi(x, t))$  for initial (left) and final (right) times.

# Numerical experiments

**Summary.** Mass preservation of a fourth-order modified operator splitting method for linear and nonlinear Schrödinger equations over longer times.

Linear (up) versus nonlinear (down) case. Uniform (left, middle) versus non-uniform (right) time grid.

# Numerical experiments

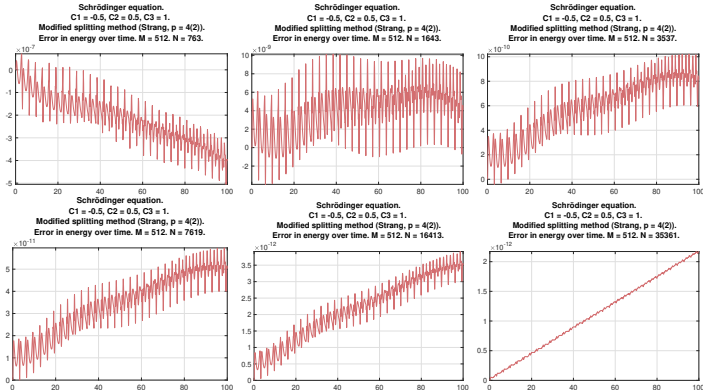

**Summary.** Energy preservation of a fourth-order modified operator splitting method for linear and nonlinear Schrödinger equations over longer times.

Linear (up) versus nonlinear (down) case. Uniform (left, middle) versus non-uniform (right) time grid.

# Numerical experiments

**Observation.** Improved energy preservation for lower tolerances. Rigorous analysis?

Nonlinear case. Tolerances in  $\{10^{-3}, 10^{-4}, 10^{-5}, 10^{-6}, 10^{-7}, 10^{-8}\}$ .  
Numbers of time steps (763, 1643, 3537, 7619, 16413, 35361) with ratios  $\approx 2.15$ .

# Numerical experiments

**Summary.** Simulation of **linear Schrödinger equations**. Application of adaptive modified operator splitting methods for **groundstate computations** (imaginary time method, normalised gradient flow) and **time evolution**.

Linear case (1d). Evolution of solution profiles  $\Re(\psi(x, t))$  in imaginary and real times.

Ground state solution given by Hermite basis function. Verify time-dependent solution  $\psi(x, t) = e^{-i\mu t}\phi(x)$ .

# Final conclusions and future work

**Summary.** Our **theoretical results** and **numerical experiments** confirm the benefits of **complex** exponential operator splitting methods for **reaction-diffusion** equations and of **modified** operator splitting methods for **complex Ginzburg–Landau-type** equations.

**General perspective.** Our investigations range from the **design** of time integration methods and their **theoretical analysis** to implementation aspects for relevant **applications**.

# Final conclusions and future work

## Future work to complete the picture.

- Rigorous **convergence analysis** of modified operator splitting methods applied to Ginzburg–Landau-type equations.
- **Extensions** to other classes of nonlinear evolution equations.

**Thank you very much!**
